1 Thread model: Deployed models

1.1 Understanding the attack

1. What level of information does the attacker have?

2. What is a model inversion attack?

1.2 Getting familiar with the dataset

The Database of Faces, (formerly "The ORL Database of Faces"), contains a set of face images taken between April 1992 and April 1994 at the AT&T Laboratories Cambridge. The database was used in the context of a face recognition project carried out in collaboration with the Speech, Vision and Robotics Group of the Cambridge University Engineering Department.

There are ten different images of each of 40 distinct subjects. For some subjects, the images were taken at different times, varying the lighting, facial expressions (open / closed eyes, smiling / not smiling) and facial details (glasses / no glasses). All the images were taken against a dark homogeneous background with the subjects in an upright, frontal position (with tolerance for some side movement). A preview image of the Database of Faces is available.

The files are in PGM format, and can conveniently be viewed on UNIX (TM) systems using the 'xv' program. The size of each image is 92x112 pixels, with 256 grey levels per pixel. The images are organised in 40 directories (one for each subject), which have names of the form sX, where X indicates the subject number (between 1 and 40). In each of these directories, there are ten different images of that subject, which have names of the form Y.pgm, where Y is the image number for that subject (between 1 and 10).

1. Plot one image from the dataset.

2. Consider a FL system with $N = 10$ clients. We wrote a code snippet that splits the dataset among the clients, such that each client holds a photo of

all the subjects. Using the FL terminology, how would you refer to such data heterogeneity?

1.3 Evaluating the performance of the attack

The attack performance is evaluated by the average SSIM over 40 people. The structural similarity index measure (SSIM) is a metric used for measuring the similarity between two images.

1. Give the precise notation for the SSIM metric.

1.4 Exercise 1

We ran the FL training process (weighted by the local dataset size) for facial recognition, assuming an IID data distribution and local epoch $E = 1$. The adversary attacks on the final deployed model by doing model inversion attack.

- Fixed the number of local epoch $E = 1$, run the code for different degree of non-iidness. Analyze the effect of the degree of non-iidness (e.g., $\alpha = \{0.1, 0.5, 0.7\}$ on the model inversion attack performance in one figure. Give an explanation to your observation and conclusion.

- Fixed the degree of non-iidness $\alpha = 0.5$, run the code for different number of local epoches. Analyze the effect of the number of local epoches (e.g., E $= \{1, 2, 3, 4, 5\}$) on the model inversion attack performance in one figure. Give an explanation to your observation and conclusion.

2 Thread model: Honest-but-curious server

2.1 Exercise 2

We enhance the capacity of the attacker to an honest-but-curious server administrator. He can has raw access to the message exchanged in FedAvg.

Assuming that the attacker executes the model inversion attack on the local returned model by a client c at time t, denoted by $\theta^c(t)$.

- Fixed the number of local epoch E $= 1$ and the degree of non-iidness $\alpha = 0.5$, run the attack on the returned model $\theta^c(t)$ on different communication round t. Analyze the effect of eavesdropped communication rounds (e.g., t $= \{1, T/4, T/3, T/2, T/1.5, T/1.25, T\}$ where T is the total number of communication rounds) on the model inversion attack performance in one figure. Give an explanation to your observation and conclusion.

- Compare the performances with the one obtained in the previous thread model. What is your observation? Try to give your explanation?
